Healthy reefs provide us with immense natural wealth. Sharks are crucial to the resilience and productivity of marine ecosystems.

Reefs Need Sharks Because...
They maintain the delicate balance in food-webs and support healthy fish stocks. Sharks generally eat large predatory fish which allows smaller, herbivorous fish and invertebrates to flourish. In turn, the herbivorous fish keep coral healthy and clean by eating the algae off coral, and thus help support a vibrant ecosystem.

Sharks Need Reefs Because...
They provide habitat and protection for smaller sharks and many other species. Some sharks rely on healthy reef habitats as breeding grounds and nurseries for their pups. Reefs also provide ‘cleaning stations’ where sharks can do a pit-stop and have parasites removed by other fish such as the cleaner wrasse.

We Need Sharks Because...
We depend on vibrant, healthy reefs that support coastal communities and a national economy through food security, tourism and recreation. Without sharks, not only does the ocean’s health suffer, so does ours.

Why Are Sharks Under Threat?
Sharks are long-lived and reproduce slowly in low numbers. Most species generally take around 10 years to reach maturity and will produce up to 4-6 young every two years¹. This makes them vulnerable to overfishing and if their populations fall too low, they may not recover. This affects not only reef health, but people who depend on reefs for tourism and food.

Sharks are Climate Champions!
Sharks help us fight global warming by protecting seagrass from overgrazing by turtles and dugongs. Seagrass draws down carbon from the atmosphere faster and stores it for longer than forests on land, helping us fight global warming².

Healthy reefs provide us with immense natural wealth. Sharks are crucial to the resilience and productivity of marine ecosystems.

Sharks are important to the health of the ocean, helping to maintain the balance of marine life and supporting coastal communities.

Reefs Need Sharks Because...
- They maintain the delicate balance in food-webs and support healthy fish stocks.
- Sharks generally eat large predatory fish, allowing smaller, herbivorous fish and invertebrates to flourish.

Sharks Need Reefs Because...

Shark Champions
(Sphyrna lewini)
Scalloped hammerhead shark

Australian blacktip reef shark
(Carcharhinus tiburo)

White tip reef shark
(Triaenodon obesus)

Tiger shark
(Galeocerdo cuvier)

Feeding Other Species
Sharks can be messy eaters. Other fish species often swoop in to scavenge the scraps for a much-needed meal.

Balancing Populations
Sharks are generally at the top of the food chain. They help keep marine food webs in check by maintaining the natural balance of species. Removing sharks could cause food webs to become unstable and collapse.

Cleaning Station
Parasites that live inside a sharks mouth or on its skin can cause irritations or harmful diseases. When sharks pop into a cleaning station, fish such as the cleaner wrasse help keep sharks healthy by eating its parasites.

Nurseries
Reefs and nearby seagrass meadows are used as breeding grounds and nurseries for some sharks. These habitats provide a plentiful source of food and protection from the open ocean for sharks in the early stages of their life.

Shelter
Reefs are complex habitats of different shapes and sizes, providing shelter for sharks and a range of other small fish and invertebrates.
